

ABSTRACT OF THE DISCLOSURE

Methods, systems and articles of manufacture for searching network information by geographic region. A geographic region may be defined as the metes and bounds of a plot of land, a location identified by a physical address, a particular structure, a global positioning system (GPS) address, etc. In each case, a geographic region is associated with a network address, such as a uniform resource locator (URL). The association between the network address and the region may be embodied in a data structure. An application then uses the data structure to resolve a query containing geographic location information indicating a current position of a requesting device.
